Cosmological Phase Transition

Spontaneously broken symmetries in field theories can be restored at sufficiently high temperatures due to thermal corrections to the effective potential

in the history of the Universe, spontaneous symmetry breaking manifests itself as a cosmological phase transition

- \mathcal{P} Consider that some scalar fields acquire nonzero vacuum expectation values (VEVs), which break a symmetry group G to a subgroup H
- 4 The manifold consisting of all degenerate vacua is the coset space G/H
- The topology of the vacuum manifold G/H can be characterized by its *n*-th homotopy group $\pi_n(G/H)$, which are formed by the homotopy classes of the mappings from an *n*-dimensional sphere S^n into G/H
- **C** A nontrivial $\pi_n(G/H)$ leads topological defects [Kibble, J. Phys. A9 (1976) 1387], as commonly predicted in grand unified theories

- \mathcal{C} Consider that some scalar fields acquire nonzero vacuum expectation values (VEVs), which break a symmetry group G to a subgroup H
- $\Delta \Delta$ The manifold consisting of all degenerate vacua is the coset space G/H
- The topology of the vacuum manifold G/H can be characterized by its *n*-th homotopy group $\pi_n(G/H)$, which are formed by the homotopy classes of the mappings from an *n*-dimensional sphere S^n into G/H
- CA nontrivial $\pi_n(G/H)$ leads topological defects [Kibble, J. Phys. A9 (1976) 1387], as commonly predicted in grand unified theories
 - **Nontrivial** $\pi_0(G/H)$: two or more disconnected components
- **Domain walls** (2-dim topological defects) **Domain walls** $\pi_1(G/H)$: incontractable closed paths
 - Cosmic strings (1-dim topological defects)
 - **Nontrivial** $\pi_2(G/H)$: incontractable spheres
 - Monopoles (0-dim topological defects)

Zhao-Huan Yu (SYSU)

Domain Walls

Omain walls (DWs) are two-dimensional topological defects which could be formed when a discrete symmetry of the scalar potential is spontaneously broken in the early Universe

II They are **boundaries** separating spatial regions with different **degenerate vacua**

Stable DWs are thought to be a cosmological problem [Zeldovich, Kobzarev, Okun, Zh.Eksp.Teor.Fiz. 67 (1974) 3]

As the Universe expands, the DW energy density decreases slower than radiation and matter, and would soon dominate the total energy density

Cosmic Strings

Collapsing Domain Walls

it is allowed if DWs collapse at a very early epoch [Vilenkin, PRD 23 (1981) 852;

Gelmini, Gleiser, Kolb, PRD 39 (1989) 1558; Larsson, Sarkar, White, hep-ph/9608319, PRD]

Such unstable DWs can be realized if the discrete symmetry is explicitly broken by a small potential term that gives an energy bias V_{bias} among the minima of the potential

The bias induces a volume pressure force acting on the DWs that leads to their collapse

Collapsing DWs can produce significant GWs [Preskill *et al.*, NPB 363 (1991) 207; Gleiser, Roberts, astro-ph/9807260, PRL; Hiramatsu, Kawasaki, Saikawa, 1002.1555, JCAP]

A stochastic gravitational wave background (SGWB) would be formed and remain to the present time

Zhao-Huan Yu (SYSU)

Spontaneously Broken Z₂ Symmetry

We study the dynamics of DWs formed through the **spontaneous breaking** of an **approximate** \mathbb{Z}_2 symmetry in a scalar field ϕ , focusing on the influence of quantum and thermal corrections induced by a \mathbb{Z}_2 -violating Yukawa coupling to Dirac fermions f in the thermal bath [QQ Zeng, X He, ZHY, JM Zheng, 2501.10059]

$$\mathcal{L} = \frac{1}{2} \partial_{\mu} \phi \partial^{\mu} \phi + \mathrm{i} \bar{f} \gamma^{\mu} \partial_{\mu} f - m_f \bar{f} f - y \phi \bar{f} f - V_0(\phi)$$

$$V_0(\phi) = -\frac{1}{2} \mu_{\phi}^2 \phi^2 + \frac{1}{3} \mu_3 \phi^3 + \frac{1}{4} \lambda_{\phi} \phi^4, \qquad \mu_{\phi}^2 > 0, \quad \lambda_{\phi} > 0$$

 \bigstar The small couplings y and μ_3 explicitly violate the \mathbb{Z}_2 symmetry $\phi o -\phi$

S Considering the **Coleman-Weinberg correction** $V_{CW}(\phi)$ and **finite-temperature correction** $V_{T}(\phi, T)$ at one-loop level, the **effective potential** becomes

$$V(\phi,T) = V_0(\phi) + V_{\rm CW}(\phi) + V_{\rm T}(\phi,T)$$

The vacuum expectation value (VEV) v_{ϕ} of ϕ corresponds to

$$\left. \frac{\partial}{\partial \phi} \left[V_0(\phi) + V_{\rm CW}(\phi) \right] \right|_{\phi = v_{\phi}} = 0$$

Zhao-Huan Yu (SYSU)

Potential Evolution and DW Tension

 \P By solving the equation of motion for the DW solution and integrating the energy density, the DW tension $\sigma_{\rm DW}$, i.e., energy per unit area, can be obtained

 $\stackrel{>}{_{\sim}}$ We choose three benchmark points (BPs) to highlight remarkable features

	$v_{\phi} [\text{GeV}]$	μ_3/v_ϕ	λ_{ϕ}	y	m_f/v_ϕ
BP1	2×10^9	-10^{-17}	0.1	2.5×10^{-5}	$4 imes 10^{-5}$
BP2	$5 imes 10^4$	-10^{-27}	0.1	$-9 imes 10^{-8}$	10^{-7}
BP3	1.5×10^{11}	-1.2148×10^{-13}	0.1	3×10^{-4}	4×10^{-4}

Domain Walls

Cosmic Strings

Summary

Backups

Evolution of Domain Walls

After DWs are created, the tension $\sigma_{\rm DW}$ acts to stretch them up to the horizon size if the friction F_f is small, and they would enter the scaling regime with energy density $\rho_{\rm DW} = \frac{\mathcal{A}\sigma_{\rm DW}}{t}$ $\mathcal{A} \approx 0.8 \pm 0.1$ is a numerical factor given by lattice simulation $\rho_{\rm DW} \propto t^{-1}$ implies that DWs are diluted more slowly than radiation and matter as the Universe expands

A If DWs are **stable**, they would soon **dominate** the evolution of the Universe, **conflicting** with cosmological observations

[Hiramatsu et al., 1002.1555]

A If DWs are **stable**, they would soon **dominate** the evolution of the Universe, **conflicting** with cosmological observations

Mowever, the potential bias $V_{\text{bias}}(T) = V(\phi_{-}, T) - V(\phi_{+}, T)$ between the false and true vacua ϕ_{-} and ϕ_{+} provides a pressure $p_{V}(T) \sim V_{\text{bias}}(T)$ acting on the DWs, against the tension force per unit area $p_{T}(T) \sim \rho_{\text{DW}}(T)$

This makes the DWs collapse and the false vacuum domains shrink

[Hiramatsu et al., 1002.1555]

SGWB Spectrum from Collapsing DWs

The SGWB from collapsing DWs can be estimated by numerical simulations [Hiramatsu, Kawasaki, Saikawa, 1002.1555, 1309.5001, JCAP]

 \swarrow The present SGWB spectrum induced by collapsing DWs can be evaluated by

$$\Omega_{\rm GW}(f)h^2 = \Omega_{\rm GW}^{\rm peak}h^2 \times \begin{cases} \left(\frac{f}{f_{\rm peak}}\right)^3, & f < f_{\rm peak} \\ \frac{f_{\rm peak}}{f}, & f > f_{\rm peak} \end{cases}$$

$$\Omega_{\rm GW}^{\rm peak} h^2 = 7.2 \times 10^{-18} \ \tilde{\epsilon}_{\rm GW} \mathcal{A}^2 \left[\frac{g_{*s}(T_{\rm ann})}{10} \right]^{-4/3} \left[\frac{\sigma_{\rm DW}(T_{\rm ann})}{1 \ {\rm TeV}^3} \right]^2 \left(\frac{T_{\rm ann}}{10 \ {\rm MeV}} \right)^{-4} f_{\rm peak} = 1.1 \times 10^{-9} \ {\rm Hz} \ \left[\frac{g_{*}(T_{\rm ann})}{10} \right]^{1/2} \left[\frac{g_{*s}(T_{\rm ann})}{10} \right]^{-1/3} \frac{T_{\rm ann}}{10 \ {\rm MeV}}$$

1 $\tilde{\epsilon}_{\rm GW} = 0.7 \pm 0.4$ is derived from numerical simulation

SGWB Spectra with and without the Fermion

 \checkmark A decrease of $T_{\rm ann}$ by one order of magnitude would increase $\Omega_{\rm GW}^{\rm peak}h^2$ by four orders of magnitude and decrease $f_{\rm peak}$ by one order of magnitude

The differences between the SGWB spectra predicted by the scenarios with and without the fermion could potentially be verified by future GW experiments

Cosmic String Tension

 $\square A network of cosmic strings would be formed in the early Universe after the spontaneous breaking of the <math display="inline">U(1)_X$ gauge symmetry

I The tension of cosmic string μ (energy per unit length) can be estimated as

$$\mu \simeq \begin{cases} 1.19\pi v_{\Phi}^2 b^{-0.195}, & 0.01 < b < 100, \\ \frac{2.4\pi v_{\Phi}^2}{\ln b}, & b > 100, \end{cases}$$

[Hill, Hodges, Turner, PRD 37, 263 (1988)]

a As $\mu \propto v_{\Phi}^2$, a high symmetry-breaking scale v_{Φ} would lead to cosmic strings with high tension

Denoting G as the Newtonian constant of gravitation, the dimensionless quantity $G\mu$ is commonly used to describe the tension of cosmic strings

$$\phi \equiv \frac{2q_{\Phi}^2 g_X^2}{\lambda_{\Phi}}$$

Gravitational Waves from Cosmic Strings

According to the analysis of string dynamics, the intersections of long strings could produce closed loops, whose size is smaller than the Hubble radius

Cosmic string loops could further fragment into **smaller loops** or reconnect to **long strings**

Loops typically have localized features called "cusps" and "kinks"

The relativistic oscillations of the loops due to their tension emit Gravitational Waves (GWs), and the loops would shrink because of energy loss

A Moreover, the cusps and kinks propagating along the loops could produce GW bursts [Damour & Vilenkin, gr-qc/0004075, PRL]

Power of Gravitational Radiation

At the emission time $t_{\rm e}$, a cosmic string loop of length l emits GWs with frequencies $f_{\rm e} = \frac{2n}{l}$ $M = 1, 2, 3, \cdots$ denotes the harmonic modes of the loop oscillation

Denoting P_n as the power of gravitational radiation for the harmonic mode n in units of $G\mu^2$, the total power is given by $P = G\mu^2 \sum P_n$

III According to the simulation of smoothed cosmic string loops [Blanco-Pillado & Olum, 1709.02693, PRD], P_n for loops in the radiation and matter eras are obtained

The total dimensionless power
$$\Gamma = \sum_{n} P_n$$
 is estimated to be ~ 50
For comparison, analytic studies imply $P_n \simeq \frac{\Gamma}{\zeta(q)n^q}$ with $q = \frac{4}{3}, \frac{5}{3}, 2$ for cusps,
kinks, and kink-kink collisions

Stochastic GW Background Induced by Cosmic Strings

The energy of cosmic strings is converted into the energy of GWs, and an SGWB is formed due to incoherent superposition

The SGWB energy density $ho_{\rm GW}$ per unit frequency at the present is

$$\frac{\mathrm{d}\rho_{\mathrm{GW}}}{\mathrm{d}f} = G\mu^2 \int_{t_{\mathrm{ini}}}^{t_0} a^5(t) \sum_n \frac{2nP_n}{f^2} \ n_{\mathrm{CS}}\left(\frac{2na(t)}{f}, t\right) \mathrm{d}t$$

 $rightarrow n_{\rm CS}(l,t)$ is the number density per unit length of CS loops with length l at cosmic time t

H(t) is the Hubble rate and t_{ini} is the cosmic time when the GW emissions start The SGWB spectrum is commonly represented by

$$\Omega_{\rm GW}(f) = \frac{f}{\rho_{\rm c}} \frac{{\rm d}\rho_{\rm GW}}{{\rm d}f}, \quad \rho_{\rm c} \equiv \frac{3H_0^2}{8\pi G}$$

Velocity-dependent One-scale Model

The evolution of the CS network can be described using the velocity-dependent one-scale (VOS) model [Martins & Shellard, hep-ph/9507335, PRD]

• The parameters are the correlation length L and the root-mean-square velocity v of string segments; the energy density of long strings is expressed as $\rho = \mu/L^2$

|| Introducing a dimensionless quantity $\xi\equiv L/t$, the evolution equations are

$$\begin{aligned} t\dot{\xi} &= H(1+v^2)t\xi - \xi + \frac{1}{2}\tilde{c}v, \quad t\dot{v} = (1-v^2)\left[\frac{k(v)}{\xi} - 2Htv\right]\\ \tilde{c} &\simeq 0.23, \quad k(v) = \frac{2\sqrt{2}}{\pi}(1-v^2)(1+2\sqrt{2}v^3)\frac{1-8v^6}{1+8v^6} \end{aligned}$$

The solutions converge to constant values [Marfatia & YL Zhou, 2312.10455, JHEP]:

 $\xi_{\rm r} = 0.271, \quad v_{\rm r} = 0.662, \quad {\rm radiation-dominated (RD) \ era}$

 $\xi_{\rm m} = 0.625, \quad v_{\rm m} = 0.582, \quad {\sf matter-dominated} \ ({\sf MD}) \ {\sf era}$

 \clubsuit This implies that the CS network quickly evolves into a linear scaling regime characterized by $L \propto t$

Cosmological observations can hardly date back to eras prior to big bang nucleosynthesis (BBN)

Warious hypotheses beyond the standard cosmic history predating BBN are possible, such as an early matter-dominated (EMD) era, a kination-dominated era, and an intermediate inflationary era

Traditional electromagnetic detection methods are ineffective when the Universe was opaque to photons

Cosmological observations can hardly date back to eras prior to big bang nucleosynthesis (BBN)

Warious hypotheses beyond the standard cosmic history predating BBN are possible, such as an early matter-dominated (EMD) era, a kination-dominated era, and an intermediate inflationary era

Traditional electromagnetic detection methods are ineffective when the Universe was opaque to photons

W Nonetheless, **GWs** can **propagate freely** through space, preserving information from the early Universe and reaching us in the present day

We study how the SGWB spectrum originated from a preexisting CS network is modified by an EMD era [SQ Ling & ZHY, 2502.16576]

Origin of the Early Matter-dominated Era

 \bigvee Consider dark matter (DM) dilution mechanism as the origin of the EMD era $\stackrel{\text{\tiny def}}{\rightarrow}$ Thermal production of a light DM candidate X with low annihilation cross sections typically results in an overproduction problem

Moverproduction can be mitigated by entropy injection from the decays of a dilutor particle Y, which dominates the Universe for a period, inducing an EMD era X Taking the minimal left-right symmetric model as an example, where the lightest and next-to-lightest right-handed neutrinos N_1 and N_2 can serve as X and Y

🌹 The related Boltzmann equations are

$$\frac{d\rho_Y}{dt} + 3H\rho_Y = -\Gamma_Y \rho_Y$$
$$\frac{d\rho_X}{dt} + 4H\rho_X = yB_X \Gamma_Y \rho_Y$$
$$\frac{d\rho_{\rm SM}}{dt} + 4H\rho_{\rm SM} = (1 - yB_X)\Gamma_Y \rho_Y$$

Cosmic Strings

Friction on the Domain Walls

The interaction between a domain wall and the f fermions in the thermal bath induces friction on the wall as it moves in the plasma

The friction force per unit area exerted on the DW is

$$F_f = rac{2}{\pi^2} rac{1}{1 - v_{
m DW}^2} \int_0^{+\infty} \int_{-\infty}^{+\infty} R(p_x) \, rac{(p_x - \omega v_{
m DW})^2}{\omega - p_x v_{
m DW}} rac{1}{{
m e}^{\omega/T} + 1} \, p_\perp \, {
m d} p_x \, {
m d} p_\perp$$

The reflection probability $R(p_x)$ can be estimated by considering one-dimensional scattering of a free particle off a step potential

 $figure{}$ F_f decreases exponentially due to the Boltzmann suppression at low temperatures

The friction is negligible when evaluating the **annihilation temperature** T_{ann} for the BPs

DM Dilution Mechanism

^(*) A long-lived dilutor Y has mass m_Y much larger than m_X can effectively address the overproduction problem of X particles

Tirst, during the RD era, both Y and X particles decouple relativistically at a similar temperature, resulting in comparable yields, $Y_Y \simeq Y_X$

^(a) Second, because of $m_Y \gg m_X$, Y particles become nonrelativistic at a relatively high temperature, while X particles remain relativistic

Consequently, *Y* particles quickly dominate the energy density of the Universe, initiating an EMD era

• Finally, when the lifetime of *Y* particles comes to an end, they decay into SM particles and *X* particles, injecting entropy and consequently diluting the energy density ρ_X of *X* particles

[Nemevšek & Y Zhang, 2206.11293, PRL]

sm X Y (sm X)

Minimal Left-right Symmetric Model

 Υ The DM candidate is $X = N_1$, and the dilutor is $Y = N_2$, which undergoes a three-body decay mediated by a right-handed gauge boson $W_{\rm R}^{\pm}$ into two charged leptons $\ell\ell'$ and one N_1

 ${ig l}$ The related right-handed charged current interactions are described by

$$\mathcal{L}_{1} = \frac{g}{\sqrt{2}} W_{\mathrm{R}}^{\mu} \left(\sum_{i=1}^{2} \bar{N}_{i} \gamma_{\mu} V_{\mathrm{PMNS}}^{R\dagger} \ell_{\mathrm{R}} + \bar{u}_{\mathrm{R}} \gamma_{\mu} V_{\mathrm{CKM}}^{\mathrm{R}} d_{\mathrm{R}} \right) + \mathrm{H.c.}$$

 N_2 decay channels include $N_2 o N_1 \ell \ell'$, $N_2 o \ell q q'$, and $N_2 o \ell W$

Benchmark parameters used in the previous slides:

$$\begin{split} m_{N_2} &= 200 \; \text{GeV}, \quad m_{N_1} = 6.5 \; \text{keV}, \quad m_{W_{\text{R}}} = 5 \times 10^7 \; \text{GeV}, \quad \tan\beta = 0.5 \\ \Gamma_{N_2} &= 2.22 \times 10^{-23} \; \text{GeV}, \quad B_X = 4.41 \times 10^{-3}, \quad y = 0.35, \end{split}$$

B_X is the **branching ratio** of the decay channel $N_2 \rightarrow N_1 \ell \ell'$ **X** y is the **energy fraction** carried away by the X particle from the Y particle **Zhao-Huan Yu** (SYSU) Domain Walls, Cosmic Strings, GWs April 2025 27 / 28

Effects of the Dilutor Decay Width and Mass

 $\oint A$ smaller dilutor decay width Γ_Y corresponds to a longer duration of the EMD era, leading to stronger suppression effects at high frequencies

A larger dilutor mass m_Y implies that the EMD era occurs earlier, and hence a higher frequency at which the suppression of the GW spectrum commences
