Past and Current High Energy Colliders

• **TEVATRON**: $p\bar{p}$ collider, 1987-2011

Circumference: 6.28 km Collision energy: $\sqrt{s} = 1.96$ TeV Luminosity: $\mathcal{L} \sim 4.3 \times 10^{32}$ cm⁻² s⁻¹ Detectors: CDF, DØ

- LEP: e^+e^- collider, 1989-2000 Circumference: 26.66 km Collision energy: $\sqrt{s} = 91 - 209$ GeV Luminosity: $\mathcal{L} \sim (2 - 10) \times 10^{31}$ cm⁻² s⁻¹ Detectors: ALEPH, DELPHI, OPAL, L3
- LHC: pp (pPb, PbPb) collider, 2009-Circumference: 26.66 km Collision energy: $\sqrt{s} = 7, 8, 13, 14$ TeV Luminosity: $\mathcal{L} \sim (1-5) \times 10^{34}$ cm⁻² s⁻¹ Detectors: ATLAS, CMS, ALICE, LHCb

The Tevatron accelerator

• ILC: International Linear Collider e^+e^- collider, $\sqrt{s} = 250 \text{ GeV} - 1 \text{ TeV}$ $\mathcal{L} \sim 1.5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$

Detectors: SiD, ILD

• CEPC: Circular Electron-Positron Collider (China)

 e^+e^- collider, $\sqrt{s}\sim 240-250$ GeV, $\mathcal{L}\sim 1.8\times 10^{34}~{\rm cm}^{-2}~{\rm s}^{-1}$

- **SPPC**: Super Proton-Proton Collider (China) pp collider, $\sqrt{s} \sim 50 - 70$ TeV, $\mathcal{L} \sim 2.15 \times 10^{35}$ cm⁻² s⁻¹
- FCC: Future Circular Collider (CERN)
 - FCC-ee: e^+e^- collider, $\sqrt{s} \sim 90 350$ GeV, $\mathcal{L} \sim 5 \times 10^{34}$ cm⁻² s⁻¹
 - FCC-hh: pp collider, $\sqrt{s} \sim 100$ TeV, $\mathcal{L} \sim 5 \times 10^{34}$ cm⁻² s⁻¹
- CLIC: Compact Linear Collider, $\sqrt{s} \sim 1-3$ TeV, $\mathcal{L} \sim 6 \times 10^{34}$ cm⁻² s⁻¹

Particle Production

[Han, arXiv:hep-ph/0508097]

• Units for cross section σ : 10^{-24} cm² = 1 b = 10^{12} pb = 10^{15} fb = 10^{18} ab

- Units for instantaneous luminosity \mathcal{L} : 10^{34} cm⁻² s⁻¹ $\simeq 315$ fb⁻¹ year⁻¹
- Integrated luminosity $\int \mathcal{L}(t) dt$ indicates the data amount
- For a process with a cross section σ , event number $N = \sigma \int \mathcal{L}(t) dt$

Colliders	Processes	SM Particles	Reconstruction	Simulation	Kinematic Variables	Homework O
Particle	e Decay					

- Particle decay is a Poisson process
- In the rest frame, the probability that a particle survives for time *t* before decaying is given by an exponential distribution:

$$P(t) = e^{-t/\tau} = e^{-\Gamma t},$$

where τ is the mean lifetime

- $\Gamma \equiv 1/\tau$ is called the decay width
- The mass of an unstable particle can be reconstructed by the total invariant mass of its products $m_{\rm inv}$, which obeys a **Breit–Wigner distribution**

$$f(m_{\rm inv}) = \frac{\Gamma}{2\pi} \frac{1}{(m_{\rm inv} - m)^2 + \Gamma^2/4}$$

The central value m is conventionally called the mass of the parent particle

Colliders Processes SM Particles Reconstruction Simulation Kinematic Variables Homework 00 00000 000000000 000000000 000 000 000 000 Partial Decay Width and Scattering Cross Section

- The probability that a decay mode j happens in a decay event is called the **branching ratio** BR(j), while $\Gamma_j = \Gamma \cdot BR(j)$ is called the **partial width** Normalization condition: $\sum_j BR(j) = \frac{1}{\Gamma} \sum_j \Gamma_j = 1$, *i.e.*, $\Gamma = \sum_j \Gamma_j$
- The partial width for an *n*-body decay mode *j*:

$$\Gamma_{j} = \frac{1}{2m} \int \prod_{i=1}^{n} \frac{d^{3}p_{i}}{(2\pi)^{3} 2E_{i}} (2\pi)^{4} \delta^{(4)} \left(p^{\mu} - \sum_{i} p_{i}^{\mu} \right) |\mathcal{M}_{j}|^{2}$$

• The cross section for a $2 \rightarrow n$ scattering process with initial states A and B:

$$\sigma = \frac{1}{2E_{\mathcal{A}}2E_{\mathcal{B}}|\mathbf{v}_{\mathcal{A}} - \mathbf{v}_{\mathcal{B}}|} \int \prod_{i=1}^{n} \frac{d^{3}p_{i}}{(2\pi)^{3}2E_{i}} (2\pi)^{4} \delta^{(4)} \left(p_{\mathcal{A}}^{\mu} + p_{\mathcal{B}}^{\mu} - \sum_{i} p_{i}^{\mu}\right) |\mathcal{M}|^{2}$$

- The 4-dimensional **delta function** respects the 4-momentum conservation
- $\bullet\,$ The invariant amplitude ${\cal M}$ is determined by the underlying physics model

Processes SM Particles Reconstruction Simulation Kinematic Variables Homework 00000

Parton Distribution Functions

Cross section for a hadron scattering process $h_1h_2 \rightarrow X$:

$$\sigma(h_1 h_2 \to X) = \sum_{ij} \int dx_1 dx_2 f_{i/h_1}(x_1, \mu_F^2) f_{j/h_2}(x_2, \mu_F^2) \hat{\sigma}_{ij \to X}(x_1 x_2 s, \mu_F^2),$$

• $\hat{\sigma}_{ij \to X}$: cross section for a parton scattering process $ij \to X$

- $f_{i/h}(x, \mu_{\rm F}^2)$: parton distribution function (PDF) for a parton *i* emerging from a hadron h with $x \equiv p_i^{\mu}/p_h^{\mu}$ at a factorization scale μ_F
- 4-momentum conservation:

$$\int_{0}^{1} dx \sum_{i} x f_{i/p}(x, \mu_{\rm F}^{2}) = 1$$

i = g, d, u, s, c, b, $\bar{d}, \bar{u}, \bar{s}, \bar{c}, \bar{b}$

• Valence quarks in a proton are *uud*:

$$\int_{0}^{1} dx [f_{u/p}(x, \mu_{\rm F}^{2}) - f_{\bar{u}/p}(x, \mu_{\rm F}^{2})] = 2$$

$$\int_{0}^{1} dx [f_{d/p}(x, \mu_{\rm F}^{2}) - f_{\bar{d}/p}(x, \mu_{\rm F}^{2})] = 1$$

Elementary Particles in the Standard Model (SM)

• Three families of fermions

- Charged leptons: electron (e), muon (μ), tau (au)
- Neutrinos: electron neutrino (v_e), muon neutrino(v_μ), tau neutrino (v_τ)
- Up-type quarks: up quark (u), charm quark (c), top quark (t)
- Down-type quarks: down quark (d), strange quark (s), bottom quark (b)

Gauge bosons

- Electroweak: photon (γ), W^{\pm} , Z^{0}
- Strong: gluons (g)
- Scalar boson: Higgs boson (H⁰)

Interactions in the Standard Model: strong interaction electromagnetic (EM) interaction weak interaction

Colliders	Processes	SM Particles	Reconstruction	Simulation	Kinematic Variables	Homework O
Com	posite Pa	rticles				

- **Nuclei**: composed of nucleons (*p* and *n*) *E.g.*, nuclei of D, T, ³He, and ⁴He
- Hadrons: strongly interacting bound states composed of valence quarks
 - Mesons: composed of a quark and an antiquark E.g., $\pi^+(u\bar{d})$, $\pi^-(d\bar{u})$, $\pi^0[(u\bar{u}-d\bar{d})/\sqrt{2}]$
 - Baryons: composed of three quarks
 E.g., proton p(uud), neutron n(udd), Λ⁰(uds)

Spin-1/2 baryon 20-plet

Spin-3/2 baryon 20-plet

Pseudoscalar meson 16-plet

Vector meson 16-plet

• Weak decay $K^+ \rightarrow \pi^+ \pi^0$, BR = 20.7%

Zhao-Huan Yu (Melbourne)

The $\bar{K}^0(s\bar{d})$ meson is the antiparticle of $K^0(d\bar{s})$, with the same mass 497.6 MeV. Under the CP transformation, $K^0 \leftrightarrow -\bar{K}^0$, so they can be mixed into two CP eigenstates: CP-even state $K_S^0 = (K^0 - \bar{K}^0)/\sqrt{2}$ and CP-odd state $K_L^0 = (K^0 + \bar{K}^0)/\sqrt{2}$. The CP conservation in weak interactions allows K_S^0 decaying into $\pi^+\pi^-$ and $\pi^0\pi^0$, but forbids K_L^0 decaying into $\pi^+\pi^-$ or $\pi^0\pi^0$, resulting in a short lifetime for K_S^0 and a long lifetime for K_L^0 .

Coordinate System in the Laboratory Frame

- The 3-momentum of a particle, **p**, can be decomposed into a component $p_{\rm L}$, which is parallel to the beam line and a transverse component $p_{\rm T}$
- The p direction can be describe by a polar angle θ ∈ [0, π] and an azimuth angle φ ∈ [0, 2π)

• The pseudorapidity $\eta \in (-\infty, \infty)$ is commonly used instead of θ

$$\eta \equiv -\ln\left(\tan\frac{\theta}{2}\right), \quad \theta = 2\tan^{-1}e^{-\eta}, \quad -\eta = -\ln\left(\tan\frac{\pi-\theta}{2}\right)$$

η	0	0.5	1	1.5	2	2.5	3	4	5	10
θ	90°	62.5°	40.4°	25.2°	15.4°	9.4°	5.7°	2.1°	0.77°	0.005°

- The 4-momentum of an on-shell particle can be described by $\{m, p_T, \eta, \phi\}$
- Particles with higher $p_{\rm T}$ are more likely related to hard scattering, so $p_{\rm T}$, rather than the energy *E*, is generally used for sorting particles or jets

Zhao-Huan Yu (Melbourne)

Colliders	Processes	SM Particles	Reconstruction	Simulation	Kinematic Variables	Homework O
Partic	le Stabi	lity				

Mean **decay length** of a relativistic unstable particle:

$$d = \beta \gamma \tau \simeq \gamma \left(\frac{\tau}{10^{-12} \text{ s}}\right) 300 \ \mu\text{m}, \quad \gamma = \frac{E}{m} = \frac{1}{\sqrt{1 - \beta^2}}$$

- Stable particles: p, e^{\pm} , γ , ν_e , ν_{μ} , ν_{τ} , dark matter particle
- Quasi-stable particles $(\tau \gtrsim 10^{-10} \text{ s})$: μ^{\pm} , π^{\pm} , K^{\pm} , n, Λ^{0} , K_{L}^{0} , etc. These particles may travel into outer layer detectors
- Particles with $\tau \simeq 10^{-13} 10^{-10}$ s: τ^{\pm} , $K_{\rm S}^0$, D^0 , D^{\pm} , B^0 , B^{\pm} , etc.

These particles may travel a distinguishable distance ($\gtrsim 100~\mu{\rm m})$ before decaying, resulting in a displaced secondary vertex

• Short-lived resonances ($\tau \lesssim 10^{-13}$ s): W^{\pm} , Z^{0} , t, H^{0} , π^{0} , ρ^{0} , ρ^{\pm} , etc. These particles will decay instantaneously and can only be reconstructed from their decay products

1 • • •						

b-jets and τ -jets

Jets originated from *b* quarks and tau leptons can be distinguished from jets originated from light quarks and gluons via tagging techniques using various discriminating variables

- *b*-jets: tagging efficiency $\sim 70\%$
 - B mesons (e.g., B^0 , B^{\pm}) result in displaced vertices
 - Numbers of soft electrons and soft muons are more than other jets
- τ -jets from hadronically decaying taus
 - 1-prong modes (BR = 50%):

1 charged meson in the decay products, medium tagging efficiency $\sim 60\%$

- 3-prong modes (BR = 15%):
 - 3 charged mesons in the decay products, medium tagging efficiency $\sim 40\%$

ME-PS	6 Match	ing				

- Matrix element: fixed order calculation for hard scattering diagrams Valid when partons are hard and well separated
- **Parton shower:** process-independent calculation based on QCD Valid when partons are **soft and/or collinear**
- ME-PS Matching: avoids double counting to yield correct distributions

Colliders	Processes	SM Particles	Reconstruction	Simulation	Kinematic Variables ●○○	Homework
Kinema	atic Vari	ables				

Although the same final states may come from various processes, we can use many **kinematic variables**, each of which catches a particular feature, to discriminate among different processes in data analyses

• Invariant mass $m_{\rm inv} \equiv \sqrt{(p_1 + p_2 + \dots + p_i)^2}$

 $m_{\rm inv}$ is commonly used to reconstruct the mass of an unstable particle from its decay products

2 Recoil mass $m_{\rm rec}$ at e^+e^- colliders

For a process e⁺ + e⁻ → 1 + 2 + ··· + n, the recoil mass of Particle 1 is constructed by $m_{1,rec} \equiv \sqrt{[p_{e^+} + p_{e^-} - (p_2 + ··· + p_n)]^2}$ For mass measurement of a particle at e⁺e⁻ colliders, we can utilize not only its decay products, but also the associated produced particles

• Missing transverse energy $\mathbf{\not{k}}_{\mathrm{T}} \equiv |\mathbf{\not{p}}_{\mathrm{T}}|, \quad \mathbf{\not{p}}_{\mathrm{T}} \equiv -\sum_{i} \mathbf{p}_{\mathrm{T}}^{i}$

 $\not\!\!E_T$ is genuinely induced by **neutrinos** or **DM particles**, but may also be a result of imperfect detection of visible particles

Zhao-Huan Yu (Melbourne)

• Scalar sum of $p_{\rm T}$ of all jets $H_{\rm T} \equiv \sum_i p_{\rm T}^{j_i}$

 $H_{\rm T}$ characterizes the energy scale of jets from hard scattering

• Effective mass
$$m_{\rm eff} \equiv \not\!\!\!E_{\rm T} + H_{\rm T}$$

 $m_{\rm eff}$ characterizes the energy scale of hard scattering processes that involve both jets and genuine $\not\!\!E_{\rm T}$ sources, *e.g.*, supersymmetric particle production

() Transverse mass $m_{\rm T}$ for semi-invisible decays

♠ For a 2-body decay process P → ν + i with a visible product ν and an invisible product i (e.g., W → ℓ ν_ℓ and $\tilde{\chi}_1^{\pm} → \pi^{\pm} \tilde{\chi}_1^0$), define

$$m_{\rm T} \equiv \sqrt{m_{\nu}^2 + m_i^2 + 2(E_{\rm T}^{\nu}E_{\rm T}^i - {f p}_{\rm T}^{
u}\cdot{f p}_{\rm T}^i)}$$
 with $E_{\rm T}^{
u,i} \equiv \sqrt{m_{\nu,i}^2 + |{f p}_{\rm T}^{
u,i}|^2}$

Zhao-Huan Yu (Melbourne)

() "Stransverse mass" m_{T2} for double semi-invisible decays

 \clubsuit For decays of a particle-antiparticle pair $P\bar{P} \rightarrow v_1 v_2 i\bar{i}$ with two visible products v_1 and v_2 and two invisible products i_1 and i_2 , define

$$m_{\mathrm{T2}}(\mu_i) = \min_{\mathbf{p}_{\mathrm{T}}^1 + \mathbf{p}_{\mathrm{T}}^2 = \mathbf{p}_{\mathrm{T}}} \left\{ \max \left[m_{\mathrm{T}}(\mathbf{p}_{\mathrm{T}}^{\nu_1}, \mathbf{p}_{\mathrm{T}}^1; m_{\nu_1}, \mu_i), m_{\mathrm{T}}(\mathbf{p}_{\mathrm{T}}^{\nu_2}, \mathbf{p}_{\mathrm{T}}^2; m_{\nu_2}, \mu_i) \right] \right\},\$$

where μ_i is a trial mass for *i* and can be set to 0 under some circumstances m_{T2} is the minimization of the larger m_T over all possible partitions $m_T = 1$ is equal to the true mass of *i*, m_{T2} will be bounded by m_P : $m_{T2} \le m_P$

- Draw one or two more Feynman diagrams for decay modes of every hadron listed in Pages 15–19
- ② Show that the $\pi^+\pi^-$ and $\pi^0\pi^0$ systems have CP = +, and explain how the CP conservation affects the lifetimes of the K_S^0 and K_L^0 mesons, as mentioned in Page 15
- Explain how the OZI rule significantly reduces the widths of the J/Ψ and Υ mesons, whose decay modes listed in Page 18
- Proof that the pseudorapidity η defined in Page 20 is the relativistic limit of the rapidity $y \equiv \tanh^{-1}(p_L/E)$
- Express every component of the 4-momentum of an on-shell particle, $p^{\mu} = (p^0, p^1, p^2, p^3)$, as a function of $\{m, p_T, \eta, \phi\}$ defined in Page 20
- Proof the statement $m_{\rm T} \leq m_p$ in Page 32
